INTERNATIONAL NOTES

SUSPECTED SMALLPOX - Honolulu, Hawaii

On April 3, a 39-year-old man arrived in Honolulu, Hawaii, and was hospitalized with a febrile illness suggestive of prodromal smallpox. Alert Quarantine Officials at the Honolulu Airport, in clearing passengers from Japan Airlines flight 062, noted one traveler who appeared ill. On questioning him, they learned he had experienced malaise for 2 days since departing New Delhi, India, on April 1. Further questioning revealed a distinct exposure to presumed smallpox 14 days prior to departure. His temperature as recorded at the Quarantine Station was 101°F. There was no rash. The patient was transported to Tripler

Hospital, Honolulu, and admitted as a case of suspected smallpox.

He left Frankfurt, Germany, on March 17, and from March 18 through 26 he visited several areas in India where smallpox was occurring. He stated that, on March 19, he was "within 10 feet of a young Indian male with presumed smallpox" in a village near Jaipur.

SUSPECTED SMALLPOX - Honolulu, Hawaii

(Continued from front page)

The patient had been vaccinated in infancy and revaccinated at ages 5 and 10 years. He was revaccinated in 1959 with an erythematous response, in 1962 with response not known, and in 1965 without clinical reaction. On March 29, just prior to leaving India, he was revaccinated with double insertion of vaccine.

On April 1, he developed a non-specific illness characterized by general malaise. On arrival in Honolulu, he demonstrated vaccination lesions described as "maximal reactions," and lymphadenopathy of the related axilla. Within 12 hours after hospitalization, the patient's temperature returned to normal levels and his symptoms subsided; no eruption appeared. He has remained afebrile through April 5.

(Reported by Dr. Robert W. Hartly, MOC, U.S. Quarantine Station, NCDC, Honolulu; Dr. W.B. Quisenberry, Director of Health, Hawaii Department of Health.)

Editorial Note:

This clinical picture is entirely consistent with a febrile response to an active vaccinal infection resulting from revaccination. However, the onset of a febrile illness in a previously vaccinated individual 14 days after a presumed exposure to smallpox is suggestive of prodromal smallpox infection. The absence of a rash does not necessarily preclude such a diagnosis, as smallpox infection may occur without cutaneous manifestations; *variola sine eruptione*, a well documented although infrequent manifestation of smallpox infection, is a syndrome characterized by a very brief period of fever, headache, mild myalgia, and malaise. There is a rapid return to normal health without the development of an eruption. Patients with this form of the disease are generally considered not to be infective although Dixon¹ suggests that they may be infective briefly during the febrile period.

Reference:

¹Dixon, C.W.: *Smallpox*. J. & A., Churchill, Ltd., London, 1962, p. 41.

SMALLPOX - Europe, India and Pakistan

As of April 5, 1967, no secondary cases have occurred among contacts of the three smallpox cases identified in Germany and Czechoslovakia (MMWR, Vol. 16, Nos. 10-12). Fifteen individuals who were exposed to the third imported case (Hanover, Germany dermatologist) on Air India flight 107 on March 23 have been located in the United States, vaccinated, and placed under surveillance by local health authorities. As of April 5, none of these persons had developed any symptoms or signs suggestive of smallpox infection.

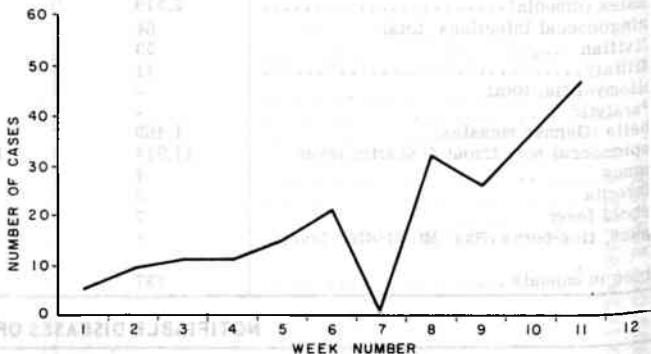

Revised notifications received by the World Health Organization during the first 10 weeks of 1967 (through week ending March 11) indicate that a total of 6,459 cases of smallpox (including imported cases) were reported from India. Provisional data compiled from the telegraphic reports show 268 additional cases for the week ending March 18, making a provisional total of 6,727 reported cases of smallpox through the first 11 weeks of 1967, as compared with 3,637 cases during a comparable period in 1966.

Dramatic increases have been noted in the cities of Bombay (Maharashtra State), Gaya (Bihar State), and Visakhapatnam (Andhra Pradesh State). In Bombay, 145 cases were reported for the week ending March 18 and 160 cases for the week ending March 25, bringing the total

for the first 12 weeks of 1967 to 1,145 cases (MMWR, Vol. 16, No. 12).

In Pakistan, 654 cases of smallpox were reported during the first 10 weeks of 1967, as compared with 647 for the similar period in 1966. High incidence is occurring in Karachi, Lahore, and Dacca (Figure 1).

EPIDEMIOLOGIC NOTES AND REPORTS
STREPTOCOCCAL INFECTIONS - Nome, Alaska

Between December 12, 1966, and January 31, 1967, three cases of rheumatic fever and one case of acute glomerulonephritis occurred among Eskimo residents of Nome, Alaska. All of the patients were hospitalized in the Alaska Native Hospital in Kotzebue. Of the three rheumatic fever patients (two 13-year-old girls and one 26-year-old male), only one was found to have beta hemolytic streptococcus on throat culture. All three, however, had high white blood cell counts, elevated erythrocyte sedimentation rates, and high antistreptolysin-O titers in addition to a murmur of mitral insufficiency. The 17-year-old male with acute glomerulonephritis developed marked proteinuria and was placed on steroids. His throat culture was positive for beta hemolytic streptococcus.

To determine the prevalence of streptococcal infection in the school children of Nome, a randomized sample of approximately one-third of the 922 school children (grades 1 through 12 in Nome School plus grades 9 through 12 in a vocational school) was selected. The sample corresponded to the estimated native-white ratio of the Nome

population as a whole and to the sex ratio in the school population. On February 16 and 17, 1967, throat cultures were obtained from the selected children. Beta hemolytic streptococci were isolated from 113 (46 percent) of the 245 children attending Nome School, and from 10 (20 percent) of the 51 students attending the vocational school (Table 2). Of the Nome School isolations, 66 percent were group A; 80 percent of those from the vocational school were group A.

Of the total of 83 group A beta hemolytic streptococcal isolates, 26 were M-typable; 24 were type 5 and two type 12. Of the M-nontypeable strains, however, 20 were found to be type 12 by the T-agglutination method. Fifteen additional strains were identified as type 11 by T-agglutination, two of which were also M type 12.

On the basis of these findings, a prophylactic program was proposed by the personnel of the Arctic Health Research Center and the Alaska Native Health Area Office. All school children were given 1.2 million units of benzathine penicillin in February 1967.

(Continued on page 108)

11	7	2	28.6	100.0
12	6	1	16.7	0
Total	51	10	19.6	80.0

*Percent of beta hemolytic streptococci

Serologic studies on blood specimens obtained from 291 children in the selected group are in progress. Preliminary results of these studies have shown sharply increased antihyaluronidase titers among individuals positive for either type 5 or type 12 streptococci, and elevated antistreptolysin-O titers, particularly among individuals who carried type 12 streptococci. In addition, type 12-specific antibody titers, as measured by the type-specific hemagglutination test, was sharply increased among individuals who carried type 12 strains. The weight of both bacteriologic and serologic evidence suggests that an extensive outbreak of type 12 streptococcal infection had occurred in Nome, and that type 5 streptococci had also been prevalent in that area.

A follow-up survey is planned in April to determine the prevalence of beta hemolytic streptococcal infection following penicillin administration, and to obtain follow-up blood specimens.

(Reported by Dr. Holman Wherritt, Alaska Native Health Area Director; Dr. Thomas McGowan, Director, Alaska Division of Public Health; Dr. James Maynard, Chief, Epidemiology Section, Arctic Health Research Center; and a team from NCDC.)

THE MORBIDITY AND MORTALITY WEEKLY REPORT, WITH A CIRCULATION OF 17,000, IS PUBLISHED AT THE NATIONAL COMMUNICABLE DISEASE CENTER, ATLANTA, GEORGIA.

DIRECTOR, NATIONAL COMMUNICABLE DISEASE CENTER DAVID J. SENCER, M.D.
 CHIEF, EPIDEMIOLOGY PROGRAM A.D. LANGMUIR, M.D.
 ACTING CHIEF, STATISTICS SECTION IDA L. SHERMAN, M.S.

IN ADDITION TO THE ESTABLISHED PROCEDURES FOR REPORTING MORBIDITY AND MORTALITY, THE NATIONAL COMMUNICABLE DISEASE CENTER WELCOMES ACCOUNTS OF INTERESTING OUTBREAKS OR CASE INVESTIGATIONS WHICH ARE OF CURRENT INTEREST TO HEALTH OFFICIALS AND WHICH ARE DIRECTLY RELATED TO THE CONTROL OF COMMUNICABLE DISEASES. SUCH COMMUNICATIONS SHOULD BE ADDRESSED TO:

THE EDITOR
